

## Lab 5

1. **Rules Framework.** Use the rules framework introduced in the lecture (see `lesson5.lecture.factorymethods2` and the diagram below) along with the startup code provided in `lesson5.labs.probl` to extend functionality of the UI to incorporate rule validations for a piece of software that supports adding Books and CDs to an inventory.

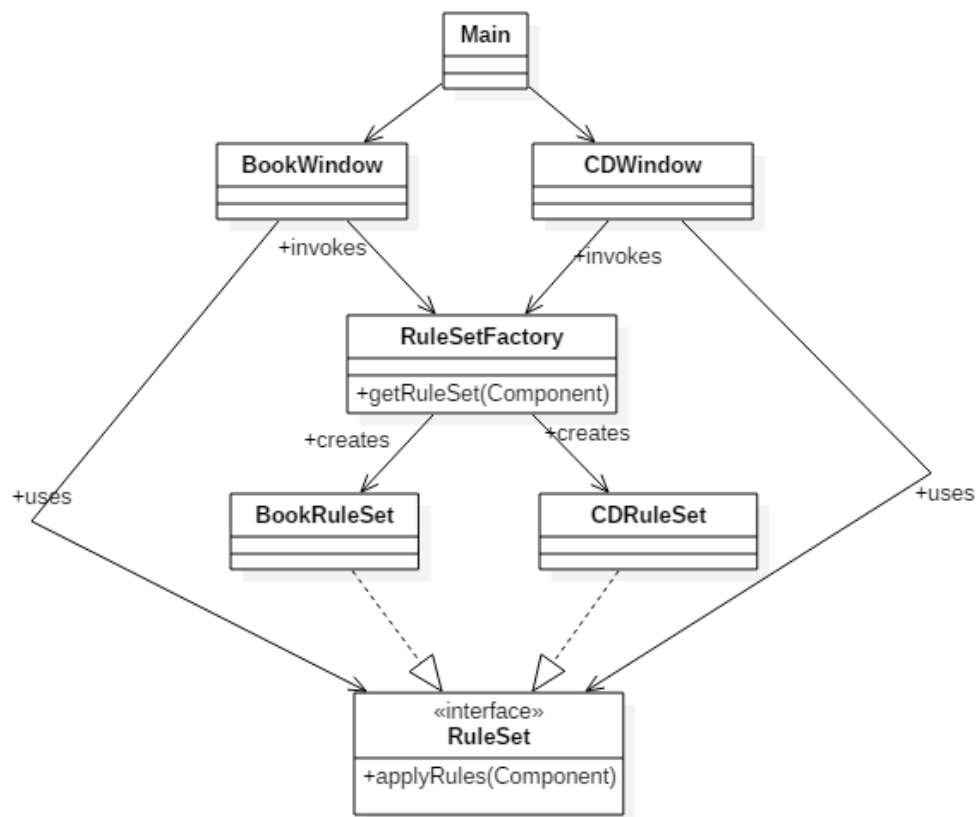

Implement the following rules:

### *Book Rules.*

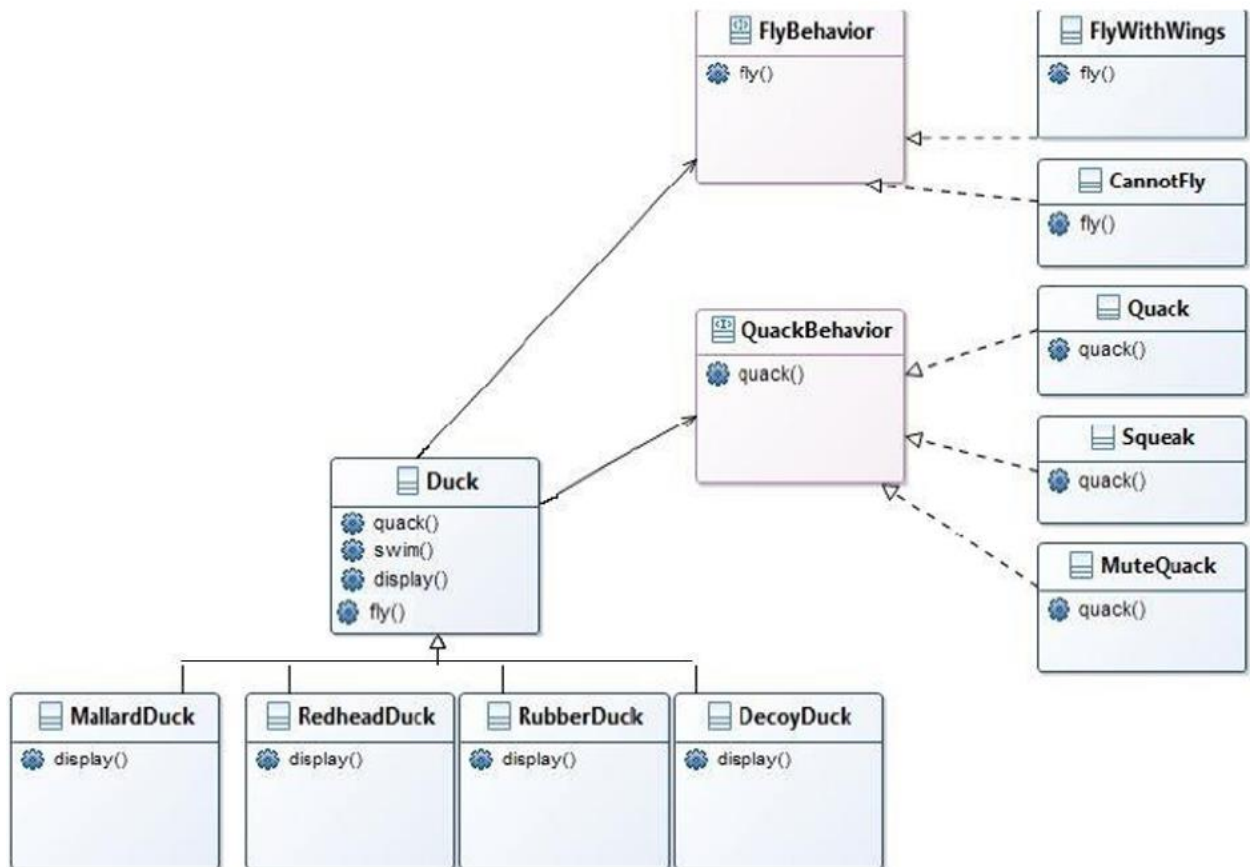

- A. All fields must be nonempty
- B. Isbn must be numeric and consist of either 10 or 13 characters
- C. If Isbn has length 10, the first digit must be 0 or 1
- D. If Isbn has length 13, the first 3 digits must be either 978 or 979
- E. Price must be a floating point number with two decimal places
- F. Price must be a number greater than 0.49.

### *CD Rules.*

- A. All fields must be nonempty
- B. Price must be a floating point number with two decimal places
- C. Price must be a number greater than 0.49.

2. In class, we made progress toward a class diagram for the DuckApp, reproduced below. How will the Duck class use the FlyBehavior and QuackBehavior interfaces? Implement the diagram in Java, and make sure the answer to this question is clear in your code. To implement the methods like fly() and quack(), just print a phrase to the console, like “Flying with wings” or “Quack by squeaking.”

To test your code, create a Main class like the following:

```
public class Main {
    public static void main(String[] args) {
        Duck[] ducks =
            {new MallardDuck(), new DecoyDuck(), new RedheadDuck(), new RubberDuck()};
        for(Duck d: ducks) {
            System.out.println(d.getClass().getSimpleName() + ":");
            d.display();
            d.fly();
            d.quack();
            d.swim();
        }
    }
}
```

Output should look like this:

```
MallardDuck:
  display
  fly with wings
  quacking
  swimming
DecoyDuck:
  displaying
  cannot fly
  cannot quack
  swimming
RedheadDuck:
  displaying
  fly with wings
  quacking
  swimming
RubberDuck:
  displaying
  cannot fly
  squeaking
  swimming
```

3. *Design Problem.* In the code for this problem, an application is provided in your startup code. This application supports login, but does not protect the Remarks and Grades screens properly. If a user is not logged in, he can still access those screens. The code must be refactored so that if a user tries to access those screens but is not logged in, then he is taken to the Login screen. Then, after successful login, the system should take him to the requested screen (Remarks or Grades), which will provide the expected data. Note that when this happens, the Remarks screen (or Grades screen) should be populated with data (the TextArea should not be empty).
4. In Lesson 2, one way of maintaining a unidirectional one-many relationship was mentioned – in that approach, creation of secondary objects (in the example, these were of type Order) was controlled by limiting visibility of the constructor to *package* level. For this problem, modify the code mentioned there (which can be found in the code folder for Lab 5) so that construction of Order objects is controlled by a factory method. The guidelines given in Lesson 2 for maintaining a one-many unidirectional association are reproduced here:

One-many Multiplicity:

- Associated with each Customer, there are zero or more Orders
- A Customer object maintains a collection of Order objects.
- Associated with each Order, there is exactly one Customer
- It is possible to navigate from a Customer to any of his Orders, but not from an Order to the owning Customer.
- *Maintaining the relationship means:*
  - when new Customer object is created, it is equipped with a (possibly empty) collection of Orders
  - it is not possible to create an Order object independent of a Customer; each new Order object must belong to the collection of Orders for some Customer.

Note: An example of using a factory method to maintain an association relationship was given in the Lesson 5 slides (see lesson5.lecture.factorymethods6 for the code showing a factory method,

and see `lesson2.lecture.unidirectional.onemany` to see another way to code a one-many unidirectional relationship).

In your implementation, make sure that **Customer**, **Order**, and **Item** all belong to the same package and that the only way any of these classes can be instantiated is by using a factory method in a factory class (which you may wish to name as `CustOrderFactory`).
